

CIX:

Before the Next Page

An idea, its limits, and the road to a working record.

The index has limits

The earliest discussion recovered so far opens a question.
It does not establish when the idea began.

1 In the earliest discussion recovered so far, I was exploring colour markers, counts and pattern indices.

2 The next question was whether the index could hold the patterns.

3 More patterns meant more pressure on the available index values.

4 A later proposal grouped patterns by frequency.

5 A fallback kept blocks that did not shrink.

6 The proposal was still a proposal.

1 I find an early report of successful restoration.

2 The reported output was larger. Reversibility alone did not remove the overhead.

3 The original test log has not been inspected here.

4 The next recovered proposal explores 15-bit rows and dictionary order.

5 Choosing five marked positions among fifteen gives 3,003 patterns, more than the 2,048 values in an 11-bit index.

6 That is a mathematical limit in the discussion, not proof of a working implementation.

Count the whole result

The recovered record now turns to a research project: count every required byte and restore the input exactly.

1 By this point, my project has a research repository and a clear rule: count every required byte and restore the input exactly.

2 I read changes for composition coding, streaming and round-trip tests. Added tests are a written milestone, not a pass result.

3 I see familiar compress-and-restore commands enter the research record.

4 The architecture in this part of my record turns toward input-derived statistics.

5 I read a small-corpus report with a narrow win on one text file and losses elsewhere. That comparison has not been independently reproduced here.

1 A checkpoint reports a 22-byte improvement in one bounded comparison. A full-corpus claim remains open.

2 Local reports list changing portfolio totals across twelve Silesia files, including established backends and structural work. These are not an official ranking or independent reproduction.

3 A billion-byte baseline was reported launched. Its launch was not a completed result.

4 The next record cancels that full baseline attempt and returns to bounded experiments. No completed full result is recorded.

5 Losing results stay in the story, alongside recorded corrections to which parts of the pipeline deserved credit.

1 Recorded changes expand the native Rust implementation's routes and compatibility work.

2 A merged integration milestone is recorded. Its first six-cell screen reports four cross-decodes and two timeouts, with 66 cells unrun. This is author-reported screening, not release acceptance.

3 Automatic selection is recorded as a comparison of complete candidate archives, including framing overhead.

1 The research target becomes a useful, fully costed implementation advantage. A broad idea is not yet proven new theory.

2 A later checkpoint reports fifty verified benchmark cells. Its matrix identity is not established here; release acceptance remains separate.

3 The record ends this research block at a benchmark pause: the native release requirements need reconciliation. No release is claimed.

Who carries the work

The record now meets the roles that carry it.
These are editorial introductions, not evidence of who attended
earlier events.

Roles around the record

These are editorial role illustrations, not evidence of earlier attendance.
Henri's proposed visual is used only in this private context.

1. This book begins with the earliest discussion recovered so far, not a proved invention date.

2. Original conversations and parts of the intervening history remain unavailable.

3. Recorded changes, reported results and independent acceptance stay separate.

4. From this context, the chronicle turns to the known record of the current month. Its open work remains open.
